

# **Tactical COMMS/ESM System for Submarines**

—

## **A Front-end Perspective**

Uwe Trautwein

South African AOC Chapter (Aardvark Roost) Conference  
25<sup>th</sup> - 26<sup>th</sup> August 2009 at CSIR Conference Centre, Pretoria

## ■ Introduction & Motivation

- See also *Proceedings Big Crow Conference Nov 2008 : Dirk Baker – The Challenges of Developing a COMINT DF & Monitoring Antenna for ... Submarine Operations*

➤ COMMS/ESM – the acronym puzzle

➤ The Submarine as a surveillance platform

## ■ System Overview

## ■ Direction Finding Capabilities

## ■ Conclusions

## COMMS

- Radio **communications** reconnaissance system
- Communications Intelligence - Strategic system component

## /ESM

- Electronic support measures – Tactical system component
- Identification and tracking of potential threats → EOB picture
- Integration into the Electronic Warfare System

Overlap : detection and interception of signals

## Covert operation

- Submarine stays submerged – only the antenna is deployed above surface
- Ideal reconnaissance platform for coastal areas and open sea

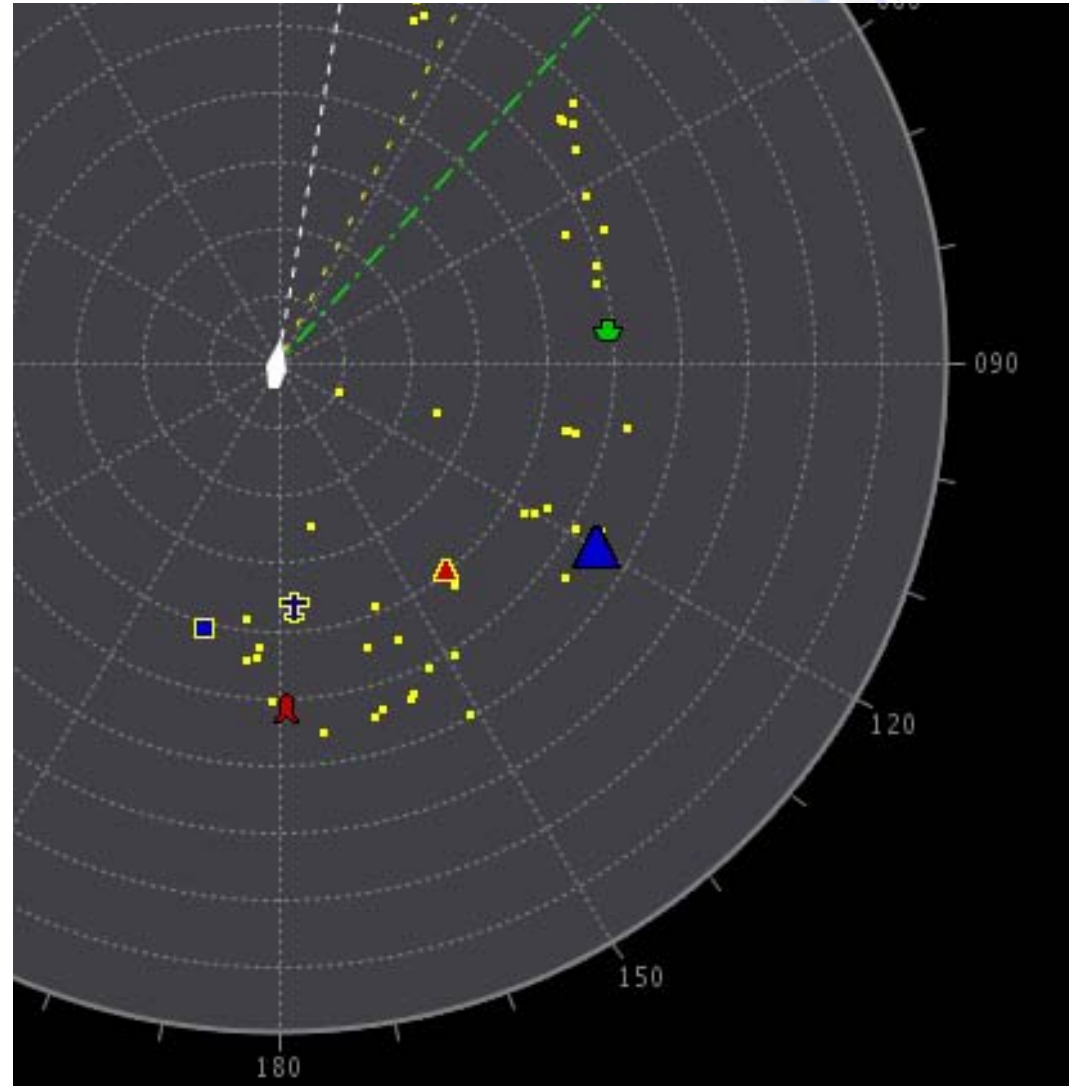

## COMMS/ESM advantage

- Extended radio horizon for lower frequency COMMS signals
  - Enables the submarine to “look” behind the horizon

Provide a bearing for a detected signal

- Only this enables ESM capabilities
- Allows to focus detection on a target area
- Prerequisite for locating
- Allows intelligence fusion with other sensor data

Allows reliable **automated** emitter detection in dense scenarios

- By jointly exploiting spectrum and azimuth information

Provide **SNR gain** for the detection of weak signals

**Separation of stations** for certain signal types

- Frequency hopper networks
- Duplex communications

Separation of multiple **co-channel signals**

## Wideband DF antenna on very compact space (300kHz – 3GHz)

- Outer antenna diameter (radome): 510 mm
- High phase accuracy requirements for the DF system
- Antenna pattern quality impairments expected due to mutual coupling
- Pressure-tight, **thick radome** - Probably affecting wave propagation
- Integrated monitoring capability

## Existing ESM ELINT antenna on top

- Electromagnetic **coupling**, space for cable feed-through

## Tight specification parameters set by the customer

- Uncompromised DF accuracy up to **30 deg elevation**
- DF and monitoring operation up to **70 deg elevation**

## System components

- Antenna
- COMINT Rack
  - All liquid cooled
- Multifunctional Consoles

## Software defined radio concept

- Medav CCT receiver with integrated FFT processor, output via Gigabit LAN interface
- General purpose computer platform for all processing tasks

## *Seamless Submarine Integration*

### MFCC for alternative systems

#### ➤ COMMS/ESM (Medav)

- Brand name: CRS-8000

**C**ommunications  
**R**econnaissance  
**S**ystem

- Radar ESM (Saab Avitronics)
- Radar
- Optronics
- Etc...

### COMMS/ESM with up to three simultaneous operator roles

- Supervisor
- Wideband operator
- Tracking operator
- Post-processing operator

## *Detail of SIGINT Antenna System*

ELINT unit

UHF arrays

Radome

VHF arrays

HF array

RF assembly

- ◆ SIGINT antenna comprises ELINT and COMINT antennas on top of **one mast**. ELINT antenna is an existing assembly.
- ◆ COMINT antenna has several key assemblies:
  - \* Radome
  - \* UHF array
  - \* VHF arrays
  - \* HF array
  - \* RF assembly
  - \* Mast interface and clamp
  - \* Wet diploops

# Basic Principle of the Correlative Interferometer for Direction Finding

- Vector correlation of the complex receive voltages with the array manifold
- The array manifold is obtained by antenna calibration measurements

- Angular power spectrum

$$\hat{\phi}_m = \arg \max_{\phi} \{|c(\phi)|\}$$

- Peak search in the angular power spectrum
- "For free": Quality criterion

Limited array size  $\rightarrow$  small phase differences  $\rightarrow$  poor correlation properties + high phase measurement accuracy

Wideband use  $\rightarrow$  trade-off must consider also the upper band edge

Very weak spatial selectivity!

High side lobe

Ideal 5 element array

## Operational aspects

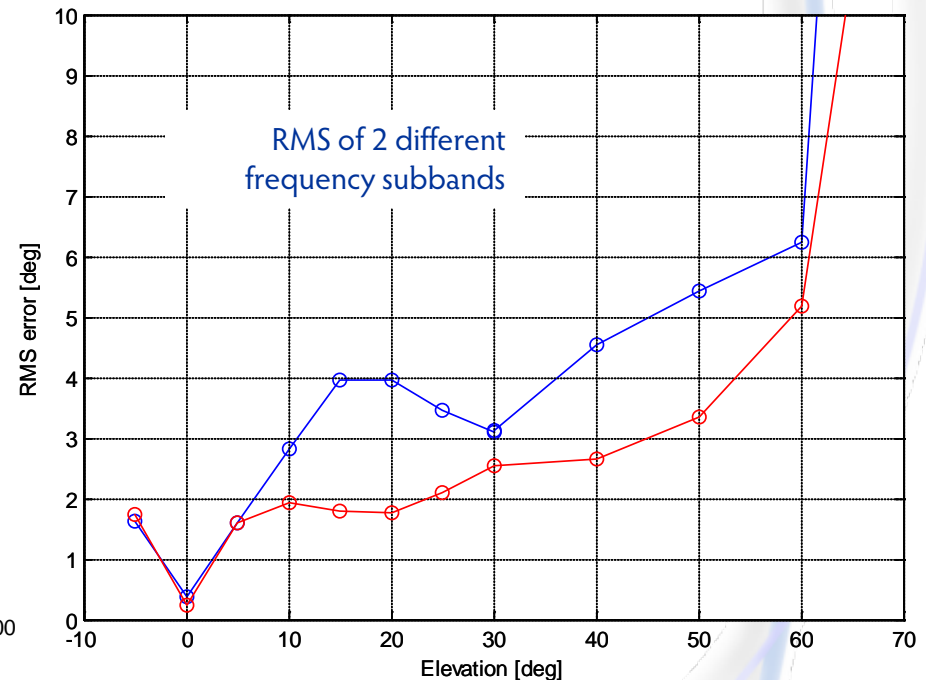

- The submarine is always a "Low altitude platform"
  - Airborne emissions
- Tolerate roll & pitch of the boat
- Discriminate between airborne and shipborne emissions

- Elevation coverage vs. Elevation estimation
  - Not exactly the same

- Degradation is frequency-dependent visible even for modest elevation angles
- Degradation can turn into complete failure
- Full 3D calibration was found to be inevitable
- Requires optimized calibration grid to limit measurement time
- **Benefit:** DF provides elevation information

- National Antenna Test Range at Paardefontein, South Africa
- Fully automated measurements

- Prototype DF System

## Factory Acceptance: Measurements over the full specified volume

- The DF accuracy (RMS azimuth error)
- The Monitoring Sensitivity (E-Field strength to achieve 10 dB SNR)

All specifications parameters are finally met

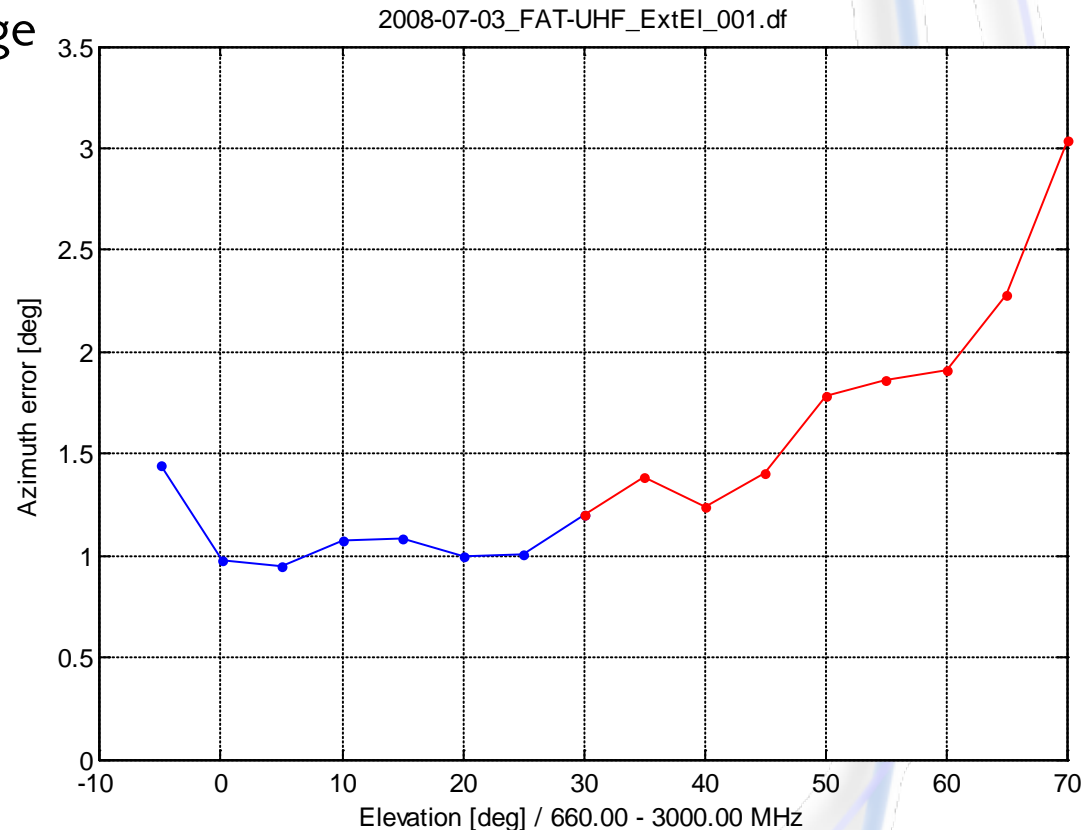

- DF accuracy typically better then 2° RMS
- Monitoring sensitivity with good margin

➤ Even for full elevation range

Comprehensive verification during FAT

- 202,150 total samples over azimuth, elevation and frequency

Very good reproducibility between systems

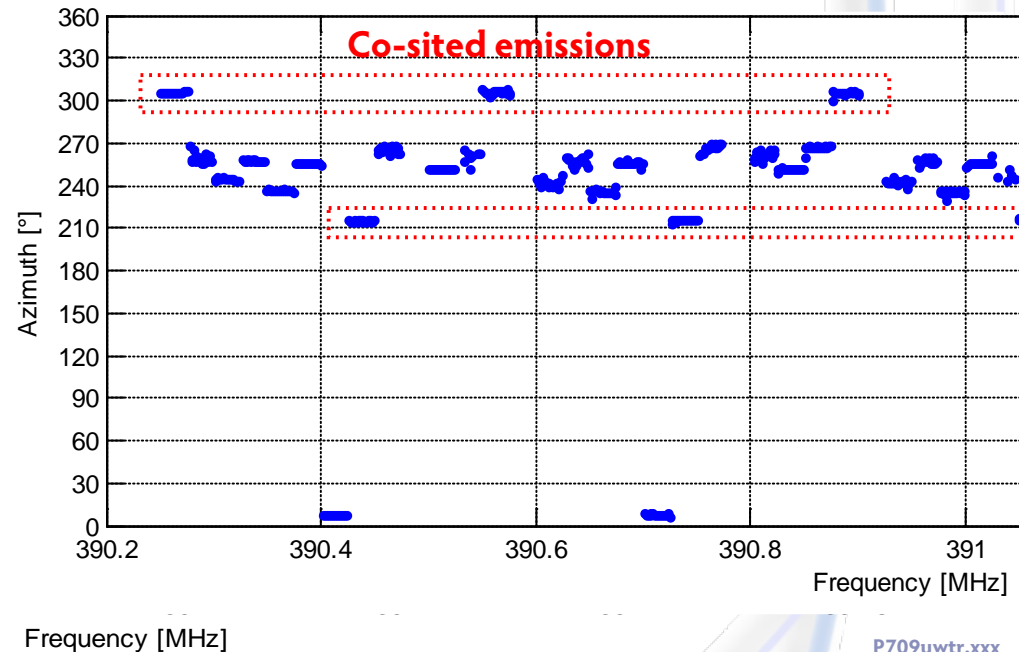

Automated Process of identifying individual transmitters incl. base parameters:  $f_c$ ,  $B$ ,  $SNR$ ,  $\phi$

- Used for alarm conditions, reporting, further analysis

Exploits 3D cluster structure of FFT based DF results

- Reliable results for many scenarios where pure power spectrum analysis must fail

Treatment of polarization in the COMINT DF context is rather sparse

HF space wave DF = mixed polarization

- Either monopoles (good Xpol) or combination of monopoles and loops

Common approach for VHF/UHF:

- The system is specified for vertical polarization

Important figure: Cross polarization (Xpol) attenuation (dB)

- Horizontal source → Vertical element response (HV)
- Small elements in compact configurations have typically a low Xpol
  - Good values are 15 dB and more, less is not uncommon

Question: What happens if a Vpol system experiences Hpol?

■ Vertically polarized source

## DF estimates for a defined DOA

■ Horizontally polarized source

## DF estimates for the same DOA

■ Completely useless

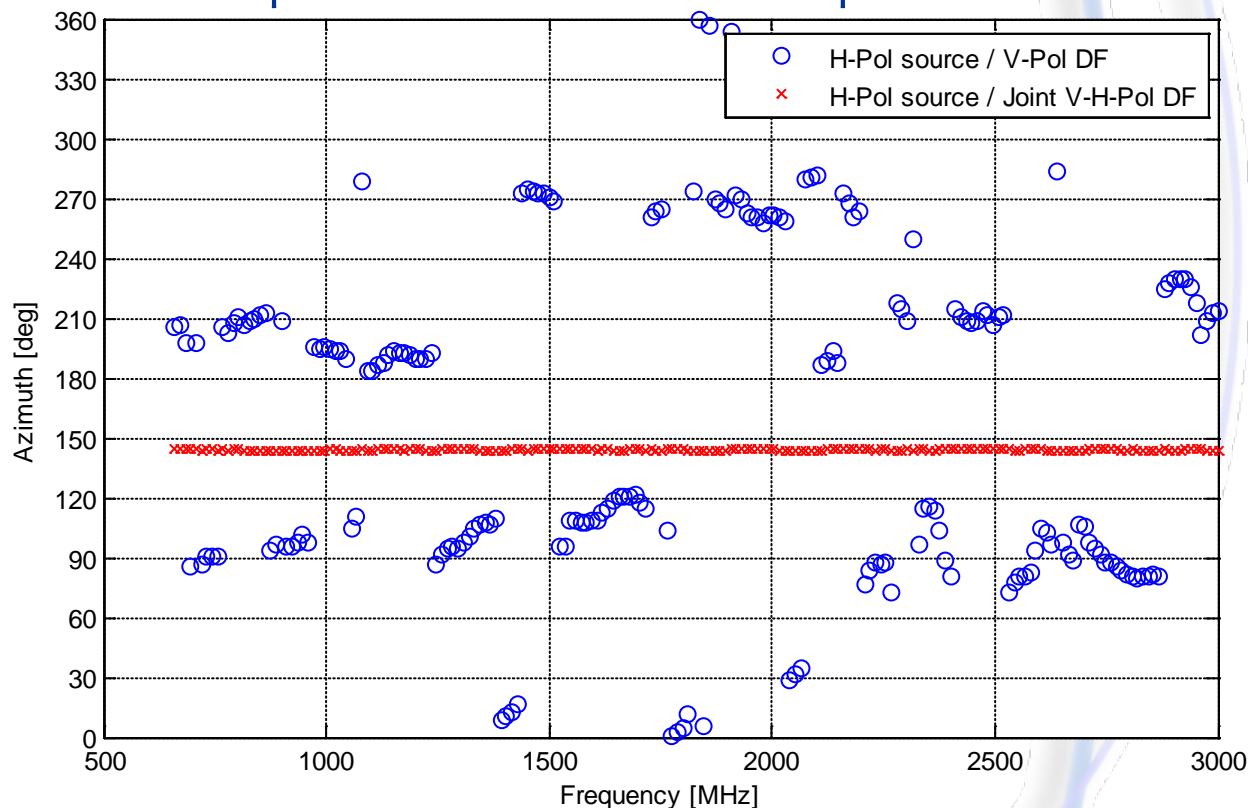

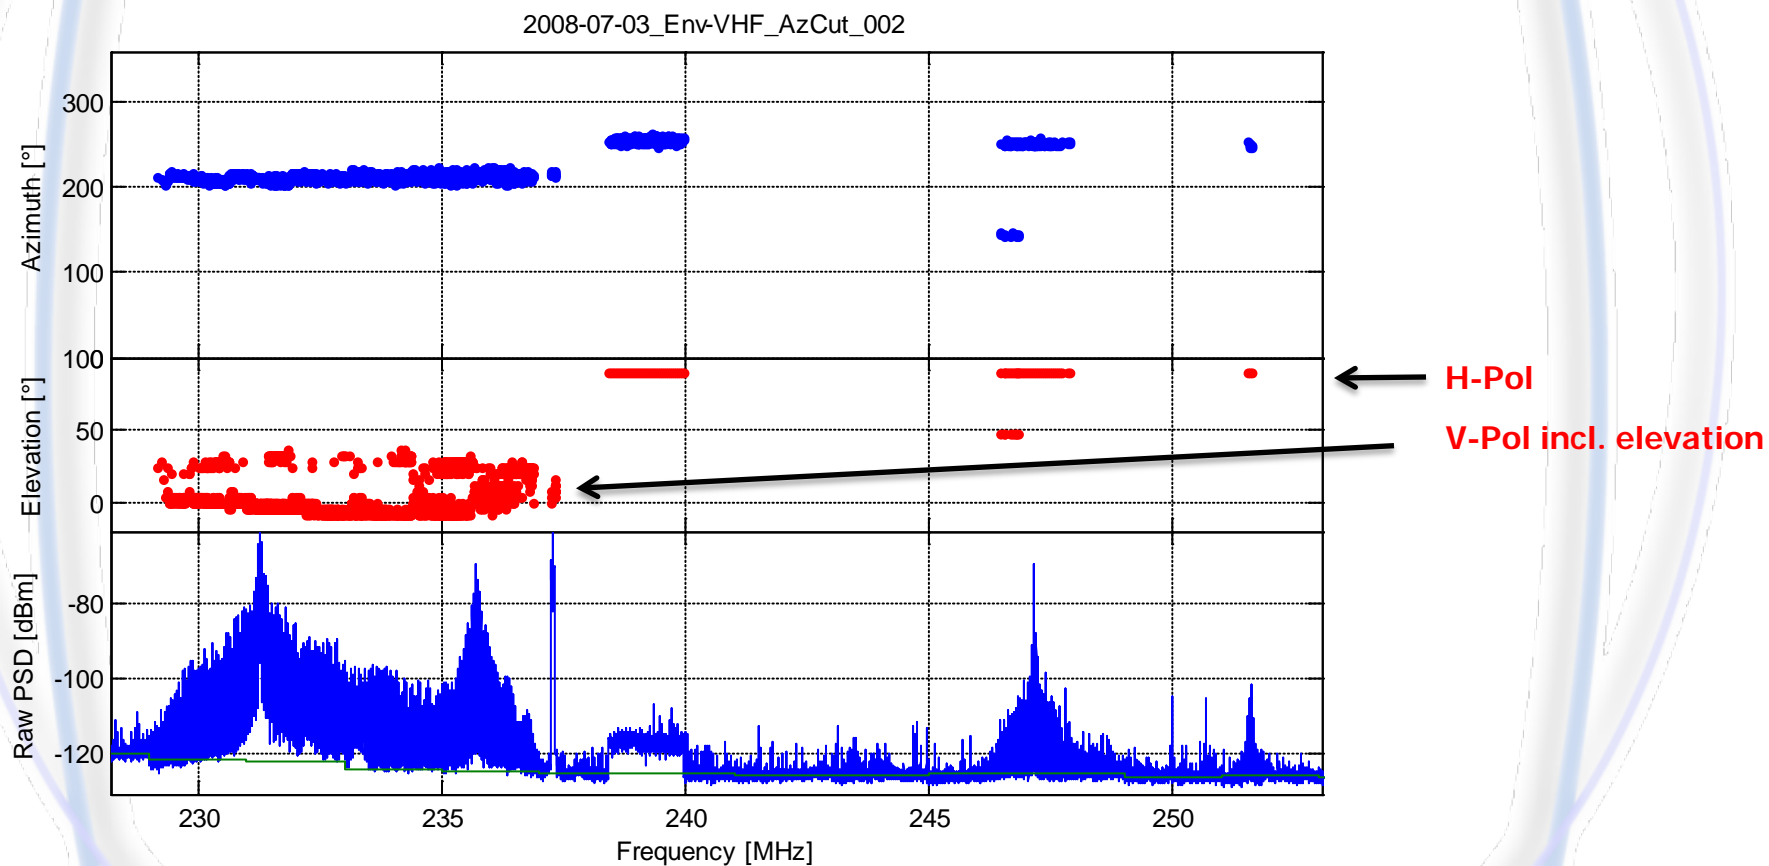

■ Horizontally polarized source

## DF estimates for the same DOA

- Valid DF estimate is retained
- Source polarization information is provided

## Demonstration of joint V-H-Pol DF in a broadcast band with both vertical and horizontal sources

Superresolution  $\neq$  high accuracy of the estimated angles

→ Resolution of multiple signals on the same carrier frequency  
(Co-channel signals)

## ■ Conventional DF system result

- Beam former := Peak search in the power azimuth spectrum
- In general undefined, depends on power ratio of the sources, the azimuth spacing, the antenna properties, etc.

## ■ Superresolution DF relies on the suppression of the co-channel signals by a weighted sum of the N antenna signals

- Theoretical limit for the number of resolvable signals is thus N-1
- Important distinction: Uncorrelated/Correlated sources

## *Superresolution DF Test Setup*

The MEDAV submarine based system can resolve up to four co-channels signals by using superresolution DF

MUSIC pseudo azimuth  
spectrum with 3 co-channel  
sources

- An ultra compact SIGINT antenna and a completely water-cooled, ruggedized COMMS/ESM system with outstanding DF capabilities was successfully developed, qualified and produced.
- It forms an integral part of the submarine's combat management system.
- It can be used for tactical reconnaissance and radio communications intelligence gathering.
- Significant contribution to upgrade the capabilities of submarines for new tasks.
